# TOWARDS A THERMODYNAMICAL APPROACH OF PROTEIN DATABASES 

R. P. Mondaini<br>S. C. de Albuquerque Neto<br>Federal University of Rio de Janeiro, RJ, Brazil<br>Centre of Technology, COPPE

OCTOBER 30, 2017

"Le savant doit ordonner ; on fait la science avec des faits comme une maison avec des pierres ; mais une accumulation de faits n'est pas plus une science qu'un tas de pierres n'est une maison.

The Scientist must set in order. Science is built up with facts, as a house is with stones. But a collection of facts is no more a science than a heap of stones is a house."

- Henri Poincaré, Science and Hypothesis

A derivation of the probability density function (pdf) for describing the formation of protein families through the solution of Fokker-Planck equations and the maximization of selected entropy measures. The present approach introduces a new statistical treatment of the formation and evolution of protein families and helps to support the classification of proteins into families and clans by methods of Statistical Mechanics.

Figure：$(m \times n)$ block of amino acids－a representative of a protein family－an element of the sample space．

Each row has $n_{l}$ amino acids，$l=1,2, \ldots, m$ ．We delete all domains such that $n_{l}<n$ and we also delete $\left(n_{l}-n\right)$ amino acids on all other domains．

The Ribosome Factory and the Organization of a Protein Family:
An example with $((m=6) \mathrm{X}(n=9))$ and 12 different amino acids: $\mathrm{V}, \mathrm{P}, \mathrm{L}$, C, F, H, I, Y, G, E, T, A.

Figure: The Ribosome Publishing Co.

The "Ribosome Player" is tossing up simultaneously 6 dodecahedron dice in this example. After this first throw, his assistant will deliver the "amino acids books" to the 1st column. After the second throw, the first librarian will collect the books of his/her column and they are delivered to the librarian of the 2nd column. Meanwhile, the first librarian will allocate the amino acids of the second throw of his/her column and the second librarian will deliver his/her amino acids to the third librarian and so on.

Dice are assumed to be fair, but there is a previous game played with tetrahedra (faces $A, C, G, U$ ) and icosahedra to follow the guidelines of the Genetic Code and actually, a successful game for organizing protein families should take into consideration unfair icosahedron dice.

Random variables -1) The probabilities of occurrence of amino acids in the columns of the $m \times n$ blocks.
$\underline{\mathrm{n}}$ vectors of 20 components to be given by

$$
\begin{gathered}
p_{j}(a)=\frac{n_{j}(a)}{m}, \quad j=1,2, \ldots, n, \quad \sum_{a} p_{j}=1 \\
a=\mathrm{A}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{~F}, \mathrm{G}, \mathrm{H}, \mathrm{I}, \mathrm{~K}, \mathrm{~L}, \mathrm{M}, \mathrm{~N}, \mathrm{P}, \mathrm{Q}, \mathrm{R}, \mathrm{~S}, \mathrm{~T}, \mathrm{~V}, \mathrm{~W}, \mathrm{Y}
\end{gathered}
$$

$n_{j}(a)$ stands for the number of occurrences of the $a$-amino acid in the $j^{\text {th }}$ column.

$$
p_{1}=\left(\begin{array}{c}
p_{1}(A) \\
\vdots \\
p_{1}(Y)
\end{array}\right), p_{2}=\left(\begin{array}{c}
p_{2}(A) \\
\vdots \\
p_{2}(Y)
\end{array}\right), \ldots, p_{n}=\left(\begin{array}{c}
p_{n}(A) \\
\vdots \\
p_{n}(Y)
\end{array}\right)
$$

2) The joint probabilities of occurrence of amino acids - the ordered pair $\underline{a b}$ on an ordered pair of columns $\underline{j k} \longrightarrow\binom{n}{2}=\frac{n(n-1)}{2}$ square matrices $p_{j k}$ of $(20)^{2}=400$ components

$$
\begin{aligned}
& p_{j k}=\frac{n_{j}(a, b)}{m}, \quad \begin{array}{c}
j=1,2, \ldots, n-1 \\
k=j+1, j+2, \ldots, n
\end{array}, \quad \sum_{a, b} p_{j k}(a, b)=1 \\
& a, b=\mathrm{A}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{~F}, \mathrm{G}, \mathrm{H}, \mathrm{I}, \mathrm{~K}, \mathrm{~L}, \mathrm{M}, \mathrm{~N}, \mathrm{P}, \mathrm{Q}, \mathrm{R}, \mathrm{~S}, \mathrm{~T}, \mathrm{~V}, \mathrm{~W}, \mathrm{Y}
\end{aligned}
$$

$n_{j k}(a, b)$ stands for the number of occurrences of the ordered pair $\underline{a b}$ in columns $\underline{j k}$.

$$
p_{j k}=\left(\begin{array}{ccc}
p_{j k}(A, A) & \ldots & p_{j k}(A, Y) \\
\vdots & \ddots & \vdots \\
p_{j k}(Y, A) & \ldots & p_{j k}(Y, Y)
\end{array}\right)
$$

These matrices can be arranged in a triangular array:

$$
p=\left(\begin{array}{cccccccc}
0 & p_{12} & p_{13} & p_{14} & \ldots & p_{1 n-2} & p_{1 n-1} & p_{1 n} \\
0 & 0 & p_{23} & p_{24} & \ldots & p_{2 n-2} & p_{2 n-1} & p_{2 n} \\
0 & 0 & 0 & p_{34} & \ldots & p_{3 n-2} & p_{3 n-1} & p_{3 n} \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \cdots & p_{n-3 n-2} & p_{n-3 n-1} & p_{n-3 n} \\
0 & 0 & 0 & 0 & \cdots & 0 & p_{n-2 n-1} & p_{n-2 n} \\
0 & 0 & 0 & 0 & \cdots & 0 & 0 & p_{n-1 n}
\end{array}\right)
$$

3) Generalized joint probabilities of occurrences of amino acids - the ordered sequence of amino acids $a_{1}, a_{2}, \ldots, a_{n-1}, a_{n}$ on an ordered set of columns $j_{1}$, $j_{2}, \ldots, j_{n-1}, j_{n} \longrightarrow\binom{n}{r}$ objects $p_{j_{1} j_{2} \ldots j_{r}}$ of $(20)^{r}$ components

$$
p_{j_{1} j_{2} \ldots j_{r}}\left(a_{1}, a_{2}, \ldots, a_{r}\right)=\frac{n_{j_{1} j_{2} \ldots j_{r}}\left(a_{1}, a_{2}, \ldots, a_{r}\right)}{m}
$$

$$
j_{1}=1,2, \ldots,(n-r+1)
$$

$$
j_{2}=(j+1),(j+2), \ldots,(n-r+2)
$$

$$
j_{r-1}=\left(j_{1}+r-2\right), \ldots,(n-1)
$$

$$
j_{r}=\left(j_{1}+r-1\right), \ldots, n
$$

$$
\begin{gathered}
1 \leq r \leq n \\
a_{1}, a_{2}, \ldots, a_{r}=\mathrm{A}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{~F}, \mathrm{G}, \mathrm{H}, \mathrm{I}, \mathrm{~K}, \mathrm{~L}, \mathrm{M}, \mathrm{~N}, \mathrm{P}, \mathrm{Q}, \mathrm{R}, \mathrm{~S}, \mathrm{~T}, \mathrm{~V}, \mathrm{~W}, \mathrm{Y}
\end{gathered}
$$

$$
\sum_{a_{1}, a_{2}, \ldots, a_{r}} p_{j_{1} j_{2} \ldots j_{r}}\left(a_{1}, a_{2}, \ldots, a_{r}\right)=1
$$

## Binomial Distribution $\longrightarrow$ Poisson Process

$$
\text { "Poissonization" } \longrightarrow \text { current process in Statistics }
$$

Discrete binomial probability distribution with discrete time is "embedded" in a Poisson process of continuous time.
Let $p\left(n_{j}(t), t\right) \longrightarrow$ probability of finding $n_{j}$ amino acids of the same kind in the $j^{\text {th }}$ column. $\sigma \longrightarrow$ the probability per unit time that a transition of an amino acid from this column will occur. $\sigma \Delta t$ is the probability that the transition will occur in the interval of time $\Delta t$. We then have $(1-\sigma \Delta t)$ as the probability that no transition will occur.
Master equation:

$$
\begin{gathered}
p\left(n_{j}(t+\Delta t), t+\Delta t\right)=\sigma \Delta t p\left(n_{j}(t)-1, t\right)+(1-\sigma \Delta t) p\left(n_{j}(t), t\right) \\
\Delta t \rightarrow 0 \longrightarrow \frac{\partial p\left(n_{j}(t), t\right)}{\partial t}=\sigma\left[p\left(n_{j}(t)-1, t\right)-p\left(n_{j}(t), t\right)\right] \\
\frac{\partial p\left(n_{0}(t), t\right)}{\partial t}=-\sigma p\left(n_{0}(t), t\right)
\end{gathered}
$$

At the "column $j=0$ " is the "Ribosome Factory". All amino acids are stored there before the start up of the process:

$$
p\left(n_{0}(0), 0\right)=1 ; \quad p\left(n_{j \neq 0}(0), 0\right)=0
$$

$$
\begin{aligned}
& p\left(n_{0}(t), t\right)=e^{-\sigma t} \\
& p\left(n_{1}(t), t\right)=e^{-\sigma t} \sigma t \\
& p\left(n_{2}(t), t\right)=e^{-\sigma t} \frac{(\sigma t)^{2}}{2} \\
& p\left(n_{2}(t), t\right)=e^{-\sigma t} \frac{(\sigma t)^{3}}{3!} \\
& \vdots \\
& p\left(n_{j}(t), t\right)=e^{-\sigma t} \frac{(\sigma t)^{n_{j}}}{n_{j}!}
\end{aligned}
$$

The moments are given by:

$$
\left\langle\left(n_{j}\right)^{k}\right\rangle=\sum_{n_{j}=0}^{\infty} n_{j} e^{-\sigma t} \frac{(\sigma t)^{n_{j}}}{n_{j}!}=e^{-\sigma t}\left(\sigma t \frac{\partial}{\partial(\sigma t)}\right)^{k}\left(\sigma t e^{\sigma t}\right)
$$

then

$$
\begin{aligned}
& \left\langle n_{j}\right\rangle=\sigma t \\
& \left\langle n_{j}^{2}\right\rangle=\sigma t+(\sigma t)^{2}
\end{aligned}
$$

Multinomial Distribution $\longrightarrow$ Maximization of Gibbs - Shannon entropy measure Probability of observing all possible configurations of $m$ amino acids in a column is found to be:

$$
\begin{gathered}
p\left(n_{j}(A), n_{j}(C), \ldots, n_{j}(Y)\right)=\frac{m!}{(20)^{m} n_{j}(A)!n_{j}(C)!\ldots n_{j}(Y)!} \\
S_{j}=-\sum_{a} \frac{n_{j}(a)}{m} \log \frac{n_{j}(a)}{m}=-\sum_{a} p_{j}(a) \log p_{j}(a)
\end{gathered}
$$

For $m \gg 1, n \gg 1$ :

$$
\frac{1}{m} \log (p)_{\max }=0=-\log 20+\left(S_{j}\right)_{\max }
$$

## Constrained Maximization

$$
\begin{gathered}
1=\int_{0}^{\infty} p\left(n_{j}(t), t\right) \mathrm{d} n_{j}(t) \\
\left\langle n_{j}(t)\right\rangle=\int_{0}^{\infty} n_{j}(t) p\left(n_{j}(t), t\right) \mathrm{d} n_{j}(t) \\
\left\langle n_{j}^{2}(t)\right\rangle=\int_{0}^{\infty} n_{j}^{2}(t) p\left(n_{j}(t), t\right) \mathrm{d} n_{j}(t) \\
0=\delta \int_{0}^{\infty}\left[-p\left(n_{j}(t), t\right) \log p\left(n_{j}(t), t\right)-\lambda_{0}(t) p\left(n_{j}(t), t\right)\right. \\
\left.-\lambda_{1}(t) n_{j}(t) p\left(n_{j}(t), t\right)-\lambda_{2}(t) n_{j}^{2}(t) p\left(n_{j}(t), t\right)\right] \mathrm{d} n_{j}(t) \\
0=\int_{0}^{\infty}\left[-\log p\left(n_{j}(t), t\right)-1-\lambda_{0}(t)-\lambda_{1}(t) n_{j}(t)-\lambda_{2}(t) n_{j}^{2}(t)\right] \\
\delta p\left(n_{j}(t), t\right) \mathrm{d} n_{j}(t) \\
\therefore p\left(n_{j}(t), t\right)=\frac{1}{Z} e^{-\lambda_{1}(t) n_{j}(t)-\lambda_{2}(t) n_{j}^{2}(t)}
\end{gathered}
$$

## Partition Function:

$$
Z=e^{1+\lambda_{0}(t)}=\int_{0}^{\infty} e^{-\lambda_{1}(t) n_{j}(t)-\lambda_{2}(t) n_{j}^{2}(t)} \mathrm{d} n_{j}(t)=\frac{1}{2 \sqrt{\lambda_{2}(t)} M(y(t))}
$$

where:

$$
\begin{aligned}
M(y(t)) & =\frac{1}{\sqrt{\pi}} \cdot \frac{e^{-y^{2}(t)}}{1-\operatorname{erf}(y(t))} \\
\operatorname{erf}(y) & =\frac{2}{\sqrt{\pi}} \int_{0}^{y} e^{-z^{2}} \mathrm{~d} z
\end{aligned}
$$

$$
y=\frac{\lambda_{1}(t)}{2 \sqrt{\lambda_{2}(t)}}
$$

$$
p\left(n_{j}(t), t\right)=2 \sqrt{\lambda_{2}(t)} M(y(t)) e^{-\lambda_{1} n_{j}(t)-\lambda_{2} n_{j}^{2}(t)}
$$

$$
\begin{gathered}
\left\langle n_{j}(t)\right\rangle=-\frac{1}{\sqrt{\lambda_{2}(t)}}(y(t)-M(y(t))) \\
\left\langle n_{j}^{2}(t)\right\rangle=\frac{1}{\lambda_{2}(t)}\left(\frac{1}{2}+y^{2}(t)-y(t) M(y(t))\right)
\end{gathered}
$$

$$
\begin{aligned}
& M^{\prime}(y)=-2 y M(y)+M^{2}(y) \\
& M^{\prime \prime}(y)=-2\left(1-2 y^{2}\right) M(y)-6 y M^{2}(y)+2 M^{3}(y)
\end{aligned}
$$

Asymptotic expansions: $\quad 0<y \ll 1, M(y) \approx \frac{1}{\sqrt{\pi}}\left(1+\frac{2}{\sqrt{\pi}}\right) y$

$$
y \gg 1, M(y) \approx y
$$

$$
\begin{gathered}
\left\langle n_{j}(t)\right\rangle=-\frac{\partial \log Z}{\partial \lambda_{1}(t)}=\frac{1}{2 \sqrt{\lambda_{2}(t)}} \frac{M^{\prime}(y)}{M(y)} \\
\left\langle n_{j}^{2}(t)\right\rangle=\frac{1}{Z} \frac{\partial^{2} Z}{\partial \lambda_{1}(t)}=-\frac{1}{4 \lambda_{2}(t)}\left(\frac{M^{\prime \prime}(y)}{M(y)}-2 \frac{M^{\prime 2}(y)}{M^{2}(y)}\right) \\
F=\left\langle n_{j}(t)\right\rangle+\left\langle n_{j}^{2}(t)\right\rangle-\frac{1}{\lambda_{1}(t)} S \\
Z=e^{-\lambda_{1} F}
\end{gathered}
$$

The Fokker-Planck equation:
Explicit dependence of the probability with the number of particles.
For an amino acid to be transfered from the $j^{\text {th }}$ column, the probability of this process can be written:

$$
p\left(n_{j}(t)-1, t\right)=p\left(n_{j}(t), t\right)-\frac{\partial p\left(n_{j}(t), t\right)}{\partial n_{j}(t)}+\frac{1}{2} \frac{\partial^{2} p\left(n_{j}(t), t\right)}{\partial n_{j}^{2}(t)}
$$

We then have from the Master Equation

$$
\begin{gathered}
p\left(n_{j}(t+\Delta t), t+\Delta t\right)=\sigma \Delta t p\left(n_{j}(t)-1, t\right)+(1-\sigma \Delta t) p\left(n_{j}(t), t\right) \\
\frac{\partial p\left(n_{j}(t), t\right)}{\partial t}+\sigma \frac{\partial p\left(n_{j}(t), t\right)}{\partial n_{j}(t)}-\frac{\sigma}{2} \frac{\partial^{2} p\left(n_{j}(t), t\right)}{\partial n_{j}^{2}(t)}=0
\end{gathered}
$$

Integrating from 0 to $\infty$ and using the boundary conditions,

$$
\lim _{n \rightarrow \infty}\left(n_{j}(t)\right)^{K} p\left(n_{j}(t), t\right)=0 ; \quad \lim _{n \rightarrow 0} p\left(n_{j}(t), t\right)=0
$$

$$
\begin{aligned}
& \sigma t=-\frac{1}{\sqrt{\lambda_{2}(y)}}(y-M(y)) \\
& \sigma t+\sigma^{2} t^{2}=\frac{1}{\lambda_{2}(y)}\left(\frac{1}{2}+y^{2}-y M(y)\right)
\end{aligned}
$$

We then look for a point $y=c$ in the parameter space such that $M^{2}(c) \approx 0$ and we consider the Taylor expansion:

$$
\begin{aligned}
& M(y) \approx M(c)+M^{\prime}(c)(y-c)+\mathcal{O}(y-c)^{2} \\
& \quad=(1-2 c(y-c)) M(c)+\mathcal{O}(y-c)^{2} \\
& \frac{1}{\lambda_{2}(y)}\left(\frac{1}{2}+2 c^{3} M(c)+\left(1-2 c^{2}\right) M(c) y\right)=\sigma t \\
& \frac{1}{\sqrt{\lambda_{2}(y)}}(y-M(c(1-2 c(y-c))))=\sigma t \\
& y=\frac{\lambda_{1}(t)}{2 \sqrt{\lambda_{2}(y)}}
\end{aligned}
$$

$$
\begin{gathered}
\lambda_{1}(y)=\frac{1+2\left(1-2 y^{2}+2 y^{3}\right) M(y)}{1+2 y M(y)}, \lambda_{2}(y)=\frac{1+2\left(1-2 y^{2}+2 y^{3}\right) M(y)}{2 \sigma t} \\
M(y) \equiv \frac{1}{\sqrt{\pi}} \frac{e^{-y^{2}}}{1-\operatorname{erf}(y)}
\end{gathered}
$$

Figure: $(M(y)-),\left(\lambda_{1}(y)-\right),\left(\lambda_{2}(y), \sigma t=1-\right),\left(\lambda_{2}(y), \sigma t=2-\right)$, $\left(\lambda_{2}(y), \sigma t=3-\right)$.

$$
p\left(n_{j}(t), t\right)=2 \sqrt{\lambda_{2}(y) \pi} \frac{e^{-\lambda_{2}(y)\left(n_{j}(t)-\frac{\sigma t}{1+2 y M(y)}\right)^{2}}}{1+\operatorname{erf}\left(\frac{\sigma t \sqrt{\lambda_{2}(y)}}{1+2 y M(y)}\right)}
$$

1) $p_{1}\left(n_{j}(t), t\right), \quad M(y) \approx 0, \quad \lambda_{2}(y)=1, \quad y=-3, \quad \sigma t=3$.
2) $p_{2}\left(n_{j}(t), t\right), \quad M(y) \approx 0.030245, \quad M^{2}(y) \approx 0, \lambda_{2}(y)=0.06333, \quad y=-1.5, \quad \sigma t=3$.
3) $p_{3}\left(n_{j}(t), t\right), \quad M(y) \approx 0.053828, \quad M^{2}(y) \approx 0, \quad \lambda_{2}(y)=0.045123, \quad y=-1.3, \quad \sigma t=3$.

Figure: $\left(p_{1}\left(n_{j}(t), t\right)-\right),\left(p_{2}\left(n_{j}(t), t\right)-\right),\left(p_{3}\left(n_{j}(t), t\right)-\right)$.
