Modelling immune cell motility

Experimental data of lymphocyte motility

Trajectories of T cell migration

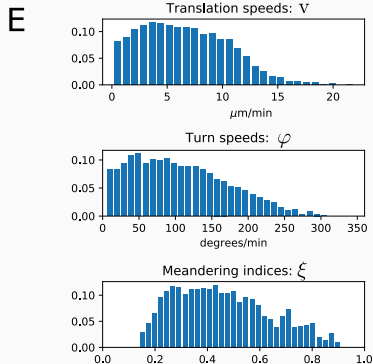

(*in vivo* microscopy of T cell zone of murine lymph nodes):

Metrics characterizing the motility of immune cells

Empirical distributions (statistical profile)

Existing types of cell motility models

- Agent-based models
- Based on classical mechanics equations (isotropic particle models, dissipative particle dynamics)
- Based on energetic formulation of cell systems (cellular Potts model, phase-field models)

Model of cell motility (isotropic particle model)

Equations governing the cell movement

$$m_i \ddot{\mathbf{x}}_i = \mathbf{F}_i = \sum_{j \neq i} \mathbf{f}_{ij} + \mathbf{f}_i^r - \mu \dot{\mathbf{x}}_i \quad \text{in } \Omega$$

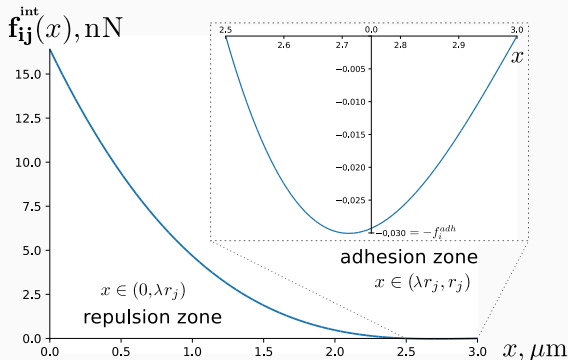

include

- dissipative friction forces $-\mu \dot{\mathbf{x}}_i$,
- cell-to-cell interaction forces $\sum_{j \neq i} \mathbf{f}_{ij}$,
- stochastic force of active (intrinsic) cell motility \mathbf{f}_i^r .

Cell-to-cell interaction forces f_{ij}

C

$$a, b : \mathbf{f}_{ij}^{\text{int}}(\lambda r_j) = \mathbf{f}_{ij}^{\text{int}}(r_j) = 0, \min_x \mathbf{f}_{ij}^{\text{int}}(x) = -f_i^{\text{adh}}$$

$$\mathbf{f}_{ij}^{\text{int}} = \frac{\mathbf{x}_i - \mathbf{x}_j}{h_{ij}} \cdot \begin{cases} -a \cdot f_i^{\text{adh}} \frac{r_j - x}{r_j} + b \cdot f_i^{\text{adh}} \frac{(r_j - x)^3}{r_j^3}, & h_{ij} < r_i + r_j, \\ 0, & h_{ij} \geq r_i + r_j \end{cases}$$

Cell-to-cell interaction forces f_{ij}

Force of cell-cell adhesion (minimum of $f_{ij}(x)$) is estimated by the data on single-cell force spectroscopy*:

$$f_{TC-TC}^{adh} \approx 0.01nN$$

$$f_{TC-DC}^{adh} \approx 1nN$$

The force of active motility f_i^r

The force of active motility *implicitly* describes the guidance of T cells by stromal structure using empirical model of correlated random walk.

- Sampling is based on empirical model for velocities IHomoCRW¹, which fits well the empirical statistical profile.
- The force sampled by rules of IHomoCRW is corrected based on model of contact inhibition of locomotion² (CIL).

¹Read et al. Leukocyte Motility Models Assessed through Simulation and Multi-objective Optimization-Based Model Selection. 2016

²Zimmermann et al. Contact inhibition of locomotion determines cell-cell and cell-substrate forces in tissues. 2016

The force of active motility (m_i , without CIL)

Every $\Delta t = 30$ seconds the magnitude and direction of force are updated. The force magnitude is sampled from normal distribution:

$$K_i^r \in |N(\mu(K^r), \sigma(K^r))|$$

The angle θ , by which the direction of force is changed, is determined by equations:

$$\alpha \in N(0, \sigma(\alpha)), \quad \theta = \alpha \cdot \left(1 - \left(\frac{K_i^r}{K_{max}^r} \right)^\beta \right),$$

where β — scalar coefficient, which parametrizes the inverse relation between translational speed and turning angle speed.

We estimated $\mu(K^r) = 3$ nN, $K_{max}^r = 3.9$ nN (compare with ~ 5 nN forces exerted by a CTL to destruct the membrane of a target cell).

The force of active motility (f_i^r , correction by CIL)

$$\begin{aligned} f_i^* &= c_{inh} \hat{m}_i + \hat{R}_i, \\ \hat{R}_i &= \sum_{j, h_{ij} \leq r_i + r_j} \frac{x_i - x_j}{h_{ij}}, \\ f_i^r &= -\frac{K_i^r f_i^*}{c_{inh} + n}, \end{aligned}$$

where K_i^r — the magnitude of motility force (without CIL-correction),

n — number of contacting neighboring cells,

\hat{m}_i — the direction of motility force,

\hat{R}_i determines the shift of force direction due to CIL,

c_{inh} — weighting coefficient determining CIL level.

Model calibration

Model calibration by experimental data

Protocol to obtain statistical profile:

F

- Protocol:
- * 30-min pre-run to randomly mix cells
 - * 10 experiments of 30 minutes length
 - * save cell positions every 30 seconds
 - * exclude cells with total displacement $< 27\text{ }\mu\text{m}$
 - * exclude cells passed through periodic boundaries

Model calibration by experimental data

Conditions for timely detection of HIV-infected cells in LNs

Conditions for timely detection of HIV-infected cells in LNs

Studying the HIV transmission in lymphoid tissue using multiscale model

Extracellular distributions of HIV virions and IFN molecules

- Free HIV virions $V(\mathbf{x}, t)$ are secreted by infected cells ($CD4^+$ T cells and DCs).
- Interferon molecules $I(\mathbf{x}, t)$ are secreted by productively infected DC.

Denoting $c = \{V, I\}$, we use reaction-diffusion equations with moving source terms:

$$\begin{aligned}\frac{\partial c}{\partial t} &= D_c \Delta c + s_c - d_c c \quad \text{in } \Omega_D, \\ c(\mathbf{x}, t) &= 0 \quad \text{on } \partial\Omega_D, \quad c(\mathbf{x}, 0) = 0 \quad \text{in } \Omega_D,\end{aligned}$$

where s_c is a source term describing secretion of the virions or molecules by $N_c(t)$ corresponding cells: $s_c(\mathbf{x}, t) = \sum_{k=1}^{N_c(t)} \rho_c I_{\Omega_k}(\mathbf{x})$.

The reaction-diffusion equations are solved numerically using ADI method on a uniform rectangular grid.

Intracellular regulation of HIV transmission

Intracellular HIV replication cycle

Intracellular HIV replication cycle

Model of cell infection (integration of viral genome)

Cell infection by HIV involves two mechanisms:

- cell-to-cell transmission, $r_{cell}^{(i)} = \hat{k}_{cell}^{(i)}(t) \cdot N_{neigh}^{(i)}(t)$,
- infection by free virions, $r_{free}^{(i)} = \hat{k}_{free}^{(i)}(t) \int_{\Omega_i} V(\mathbf{x}, t) d\mathbf{x}$,

The CD4 molecules expression is being downregulated since the start of infection: $\hat{k}_{free}^{(i)}(t) = k_{free} \cdot e^{-(t-t_{inf}^{(i)})/t_d}$ and $\hat{k}_{cell}^{(i)}(t) = k_{cell} \cdot e^{-(t-t_{inf}^{(i)})/t_d}$.

The resulting stochastic model with time-dependent rates is simulated using Temporal Gillespie Algorithm. Main idea:

$$P(\tau|t^*) = \exp \left(- \int_{t^*}^{t^*+\tau} (k_{free} V_{\Omega_i}(t) + k_{cell} N_{neigh}^{(i)}(t)) e^{-(t-t_{inf}^{(i)})/t_d} dt \right),$$

$$P(\tau|t^*) = \exp(-\mathbb{L}(t^{**}|t^*)), \quad t^{**} = t^* + \tau,$$

1. Draw normalized waiting time $\tau' = \mathbb{L}(t^{**}|t^*) \sim \text{Exp}(1)$ from standard exponential distribution.
2. Time t^{**} when a next event will occur is given implicitly by the equation $\mathbb{L}(t^{**}|t^*) = \tau'$, which is solved numerically.

Model of cell infection (results of numerical simulations)

Figure 4: Distributions of integrated proviruses in the infected cell in different infection scenarios

Model of HIV replication

$$\frac{dV_{gRNA}}{dt} = [TR] \cdot V_{int} - (2 \cdot k_{sp} \cdot (1 - \beta f_{Rev}) + k_{exp} \cdot f_{Rev} + d_{RNA}) V_{gRNA},$$

$$\frac{dV_{dsRNA}}{dt} = k_{sp} \cdot (1 - \beta f_{Rev}) V_{gRNA} - (k_{exp} + d_{RNA}) V_{dsRNA},$$

$$\frac{dV_{dsRNA}}{dt} = k_{exp} V_{dsRNA} - (d_{RNA} + k_{ISG} \cdot b_{ISG}) V_{dsRNA},$$

$$\frac{d[Tat]}{dt} = r_{Tat} V_{dsRNA} - d_{Tat} [Tat], \quad \frac{d[Rev]}{dt} = r_{Rev} V_{dsRNA} - d_{Rev} [Rev],$$

$$\frac{dV_{gRNA}}{dt} = k_{exp} \cdot f_{Rev} \cdot V_{gRNA} - (2 \cdot k_{mat} + d_{RNA} + k_{ISG} \cdot b_{ISG}) V_{gRNA},$$

$$\frac{dV_{mat}}{dt} = k_{mat} V_{gRNA} - (k_{pv} + d_{HIV}) V_{mat},$$

$$\text{where } [TR] = [TR_{cell}] + f_{Tat} \cdot [TR_{Tat}],$$

$$f_x = x / (1 + x + K_x V_{int}), x = \{Tat, Rev\}.$$

The effect of b_{ISG} on V_{gRNA} , V_{dsRNA} will be described below.

Antiviral IFN response

Model of IFN response

Stochastic model of transitions between activation states:

- activation of STAT1/2 pathway (modelled as binary variable b_{ST}) by extracellular IFN- β I_{Ω_i}
- expression of interferon stimulated genes (ISGs) (modelled as binary variable b_{ISG}), which increase degradation rates of HIV RNA in cytoplasm V_{gRNA} , V_{dsRNA}

$$\{b_{ST} = b_{ISG} = 0\} \xrightarrow{a_{STAT}} \{b_{ST} = 1, b_{ISG} = 0\} \xrightarrow{r_{ISG}} \{b_{ST} = 1, b_{ISG} = 1\},$$

where

$$a_{STAT}(t) = r_{STAT} \frac{I_{\Omega_i}(t)}{K_i + I_{\Omega_i}(t)} \text{ and } r_{ISG} \text{ are propensity rates of transitions,}$$
$$I_{\Omega_i}(t) = \int_{\Omega_i} I(\mathbf{x}, t) d\mathbf{x}.$$

The stochastic model with time-dependent rates is simulated using Temporal Gillespie Algorithm.

Intracellular dynamics of HIV and IFN in infected $CD4^+$ T cell

Numerical simulations of HIV infection dynamics in LN

Figure 6: Extracellular fields of (a) HIV virions, (b) IFN molecules, and (c) the spatial distribution of cells (dendritic cell, infected and uninfected CD4^+ T cells, specific and nonspecific CD8^+ T cells) at 48 hours postinfection. (d) Temporal kinetics of total number of HIV virions in the computational domain during 48 hours postinfection at various immune conditions.

Results

- The spatial population dynamics of immune cells and humoral factors in lymphoid organs modelled with Newton's second law and reaction-diffusion equations, respectively calibrated using experimental data for 2D consideration.
- For intracellular processes of immune cell fate regulation, both deterministic and related stochastic models are developed in pairs, that describe HIV replication and antiviral IFN response.
- The model is used to predict the necessary conditions on CTL frequencies and motility which should be induced by HIV vaccine to block local bursts of HIV infection in lymph nodes, and the effect of antiviral IFN response on HIV transmission dynamics.

Further research for development of the multiscale model
